

# Importance and methods for an accurate canopy characterisation

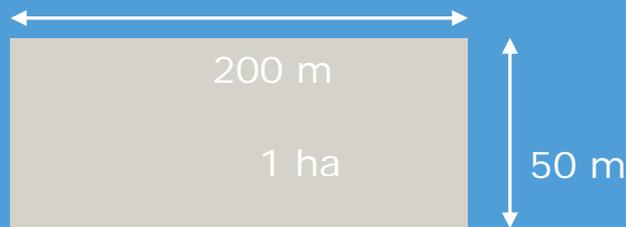

AAB – Dose expression, Barcelona, 07-11-2018

Jan van de Zande, Dirk de Hoog

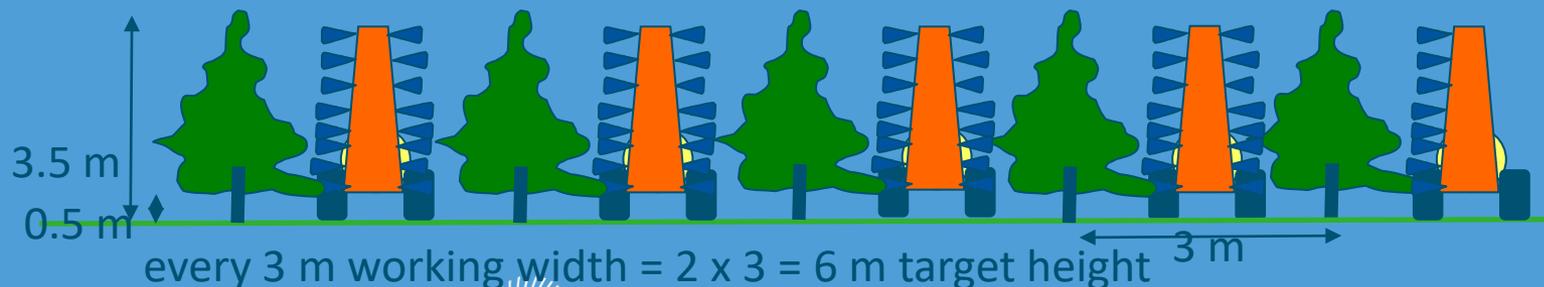

# Application of PPP

- **Field crops** – boom sprayers; downward directed spray. Spray volume and dose directly related to the treated area. E.g. L/ha spray vol. and kg/ha dose of PPP.

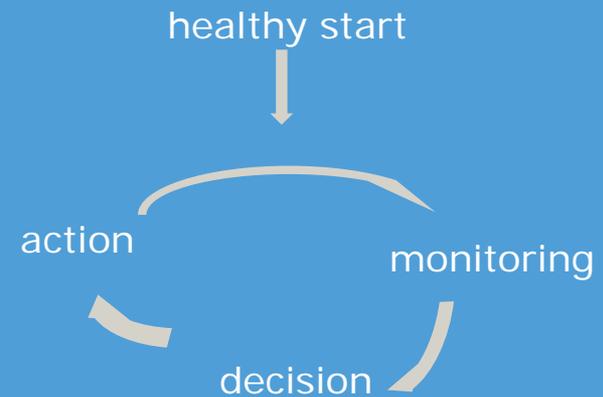

- **Bush and tree crops**; sideways and upward directed spray. Spray volume and dose related to the to be treated tree/bush canopy. L/ha spray vol., kg/ha or concentration (mL/L or %) dose of PPP.

# Ideas behind targeted application

- Reduce environmental load
- Keep a high efficacy
- Reduce risk of residue

- Apply only there where it is needed and with the amount adjusted for the crop canopy size and structure

# Introduction of Crop Adapted Spraying

- Sensing of the crop status / density
- Decision taking on the spray volume
- Actuating for the right application rate
- Based upon the knowledge of
  - Precispray 1999-2003
  - SensiSpray project within potatoes 2007-2008
  - Variable rate spraying in flower bulbs 2006-2009
  - CASA sprayer from EU project ISAFRUIT 2006-2010

# Crop Adapted Spraying – steps

- Steps in CAS

1. Gap-detection: On/off switching of nozzles
2. Spray volume / Dose determination

# Plant densities, trail and pruning systems

# Target area?

# Target area? LWA

Top level leafs 2.75 m

Height 2.75 m

Leaf height 2.50 m

Lower level leafs 0.25 m

Row spacing 3 m  
Tree spacing 1.10 m

per 100 m tree row:  
 $LWA = 100 \times 2 \times 2.50 = 500 \text{ m}^2$

# Target area? Effective LWA with sensor

$$4.4 \times 2.5 = 11.0 \text{ m}^2$$

25 x 25 cm grid  
180-38=142 cells with  
Leaves = 8.7 m<sup>2</sup>

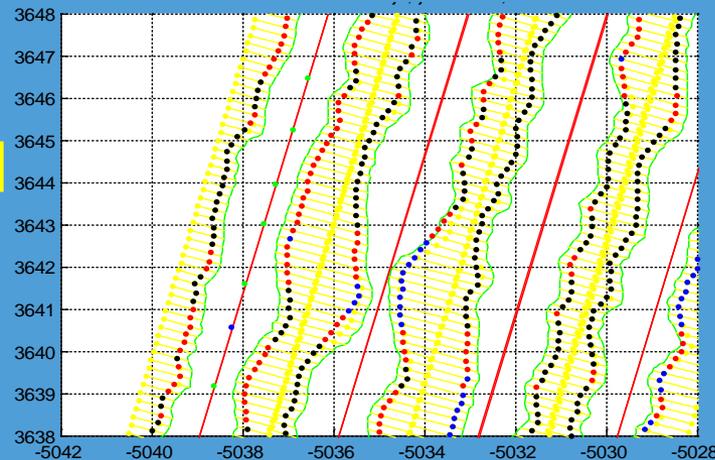

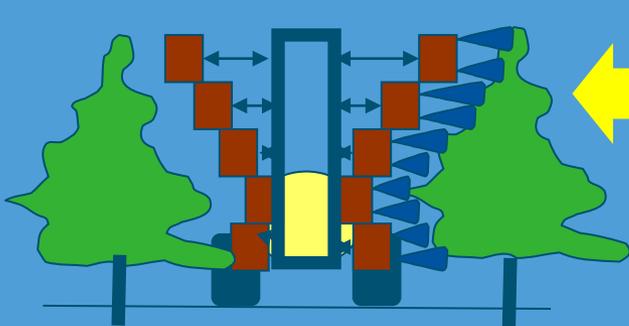

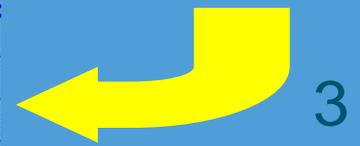

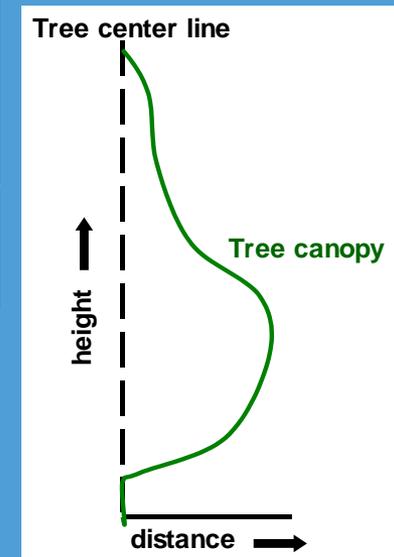

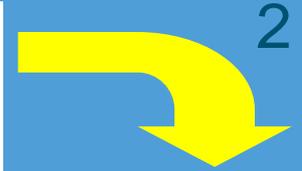

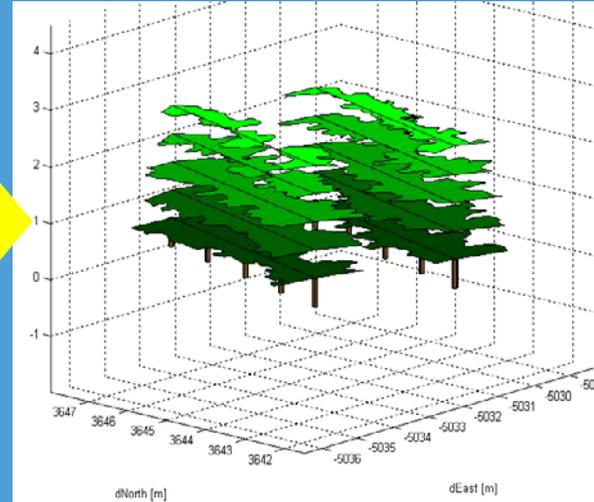

effective sensor LWA  
= 80%  
of calculated LWA

# Sensors and their use

- **Ultrasonic sensor, Laser scanner (LIDAR)** – for the detection of objects and measuring distance to the object, able to measure canopy position and canopy contour at different heights and to determine canopy volume;
- **Chlorophyll sensing** – detecting of green leaf area, able to determine green leaf position;
- Different **vision sensor** types like – RGB, depth-RGB, stereo vision, for blossom detection and (small) fruit detection for thinning activities, detection of alternation years of trees
- **Hyperspectral** images – for detection of flowers, fruits and plant stress in the leaves and potentially plant diseases.

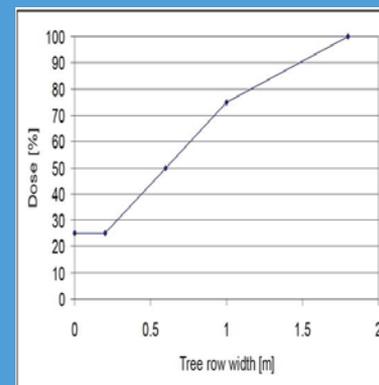

# Crop protection – fruit crops

dose related to development stage and biomass crop

# Canopy Density Spraying (CDS) in apple and pear

- Laser ranger scanner measures distance and density of leaves
- Decision algorithms adjust number of nozzles spraying
- Varioselect nozzle bodies activate one or more nozzles
- Variable air amount depending on wind speed, wind direction driving speed and direction

# CDS tested in practice by the grower - 2012 sprayflow [L/min]

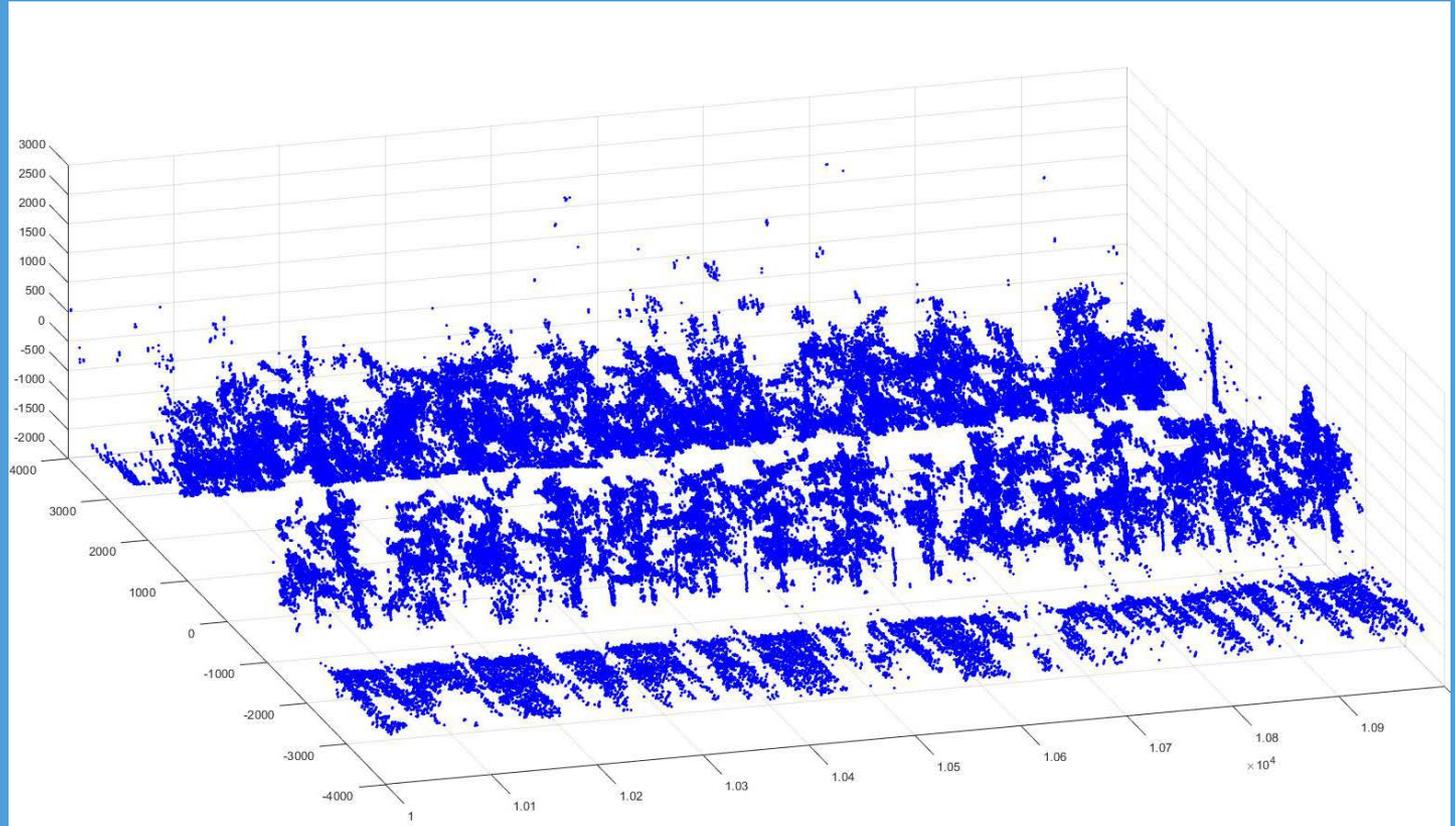

Google  
Map data ©2013 Google Imagery ©2013 Aerodata International Surveys, DigitalGlobe - Terms of Use

# Results CDS 2012 – spray deposition

- Deposition of CDS comparable to Munckhof reference =  $0.40 \mu\text{L}/\text{cm}^2$
- Deposition of the CDS was lower than of the KWH crossflow sprayer ( $0,80 \mu\text{L}/\text{cm}^2$  )
- Deposition of CDS was more homogeneous
- Spray volume reduction was 46% (BBCH 71)

# RGB camera – depth information canopy

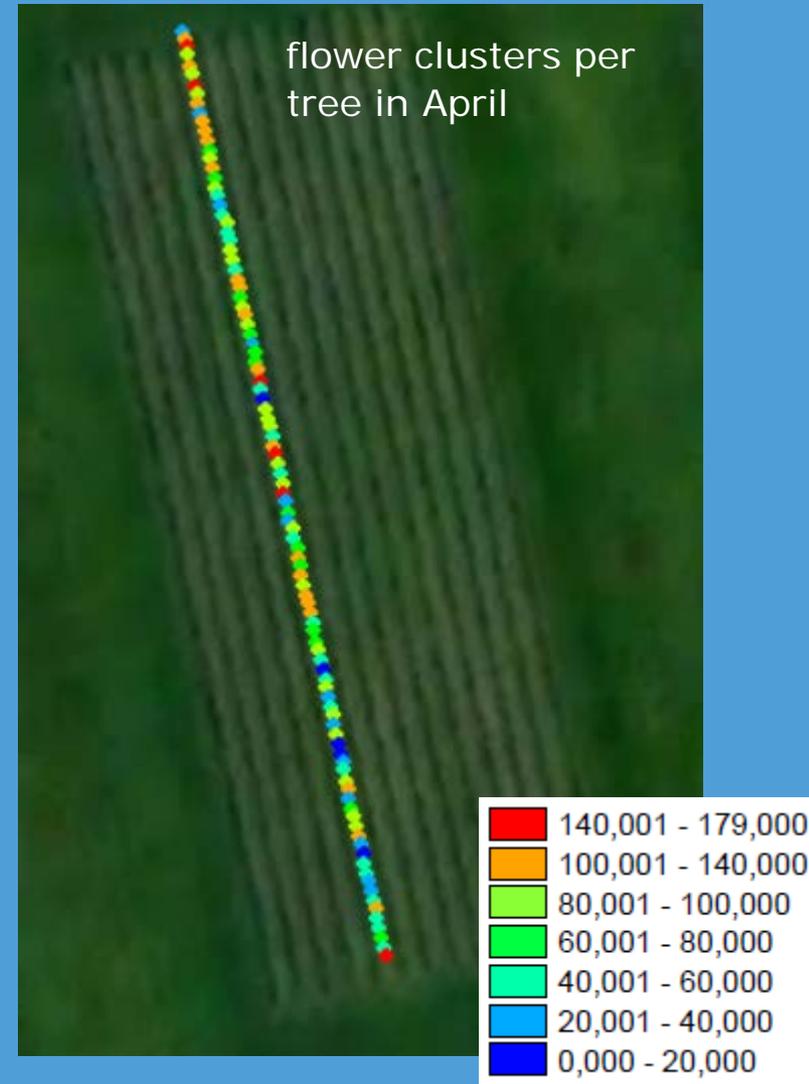

# RGB camera - Blossom detection

# Flower clusters per tree

- Large variation between individual trees
- Aim to generate task map for thinning based on this information
- Decide to thin tree on number of flower clusters;
- spray individual tree yes/no (not pollinator trees)
- Adapt dose to number of flower clusters per tree

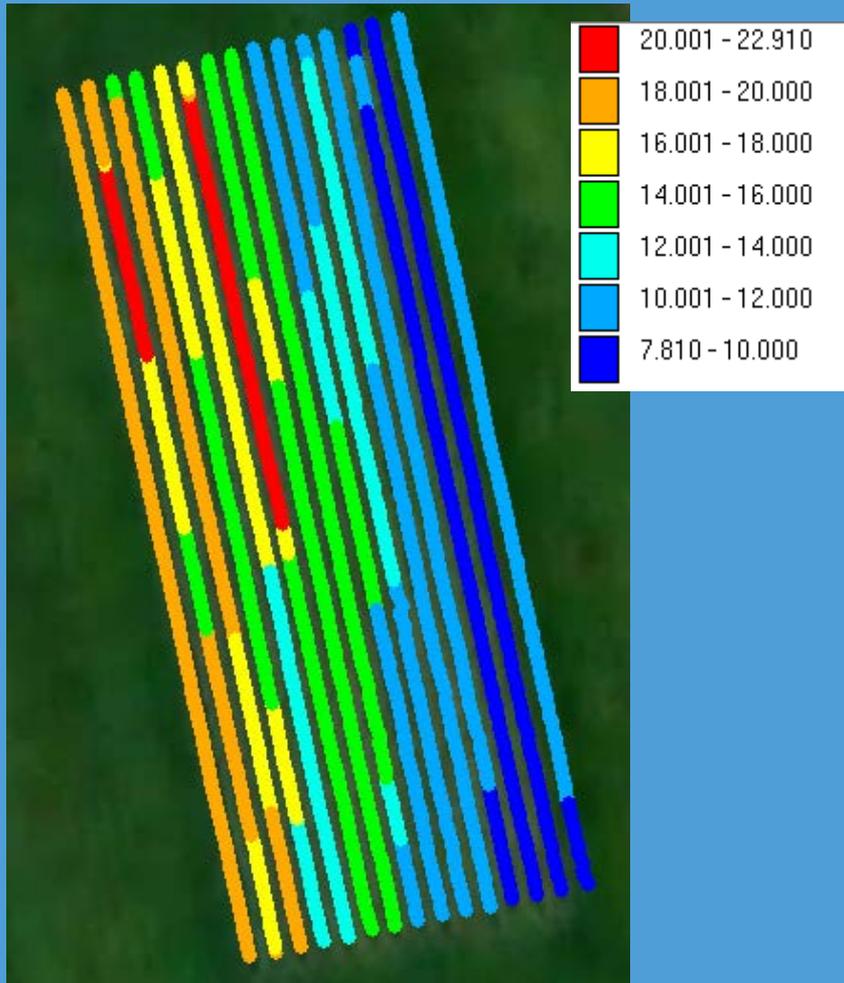

# RGB camera -Fruitlet detection (>10 mm)

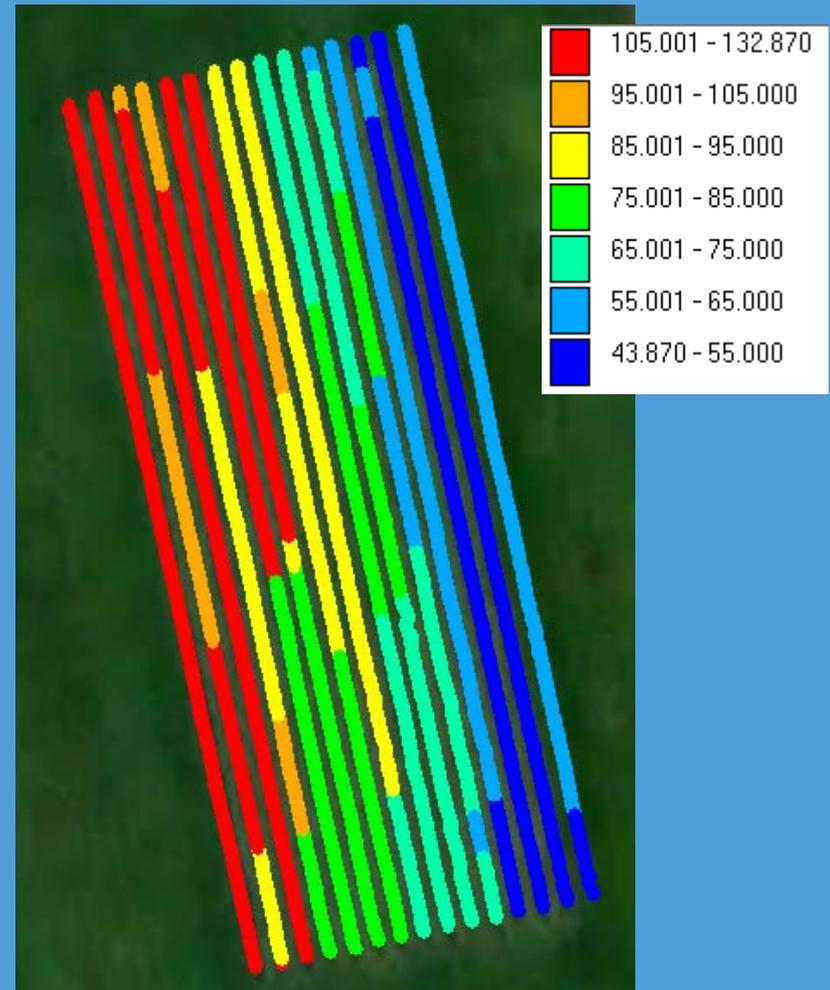

# Number of fruits per tree and apple yield

Total yield (kg/m)

Number fruits / m tree row

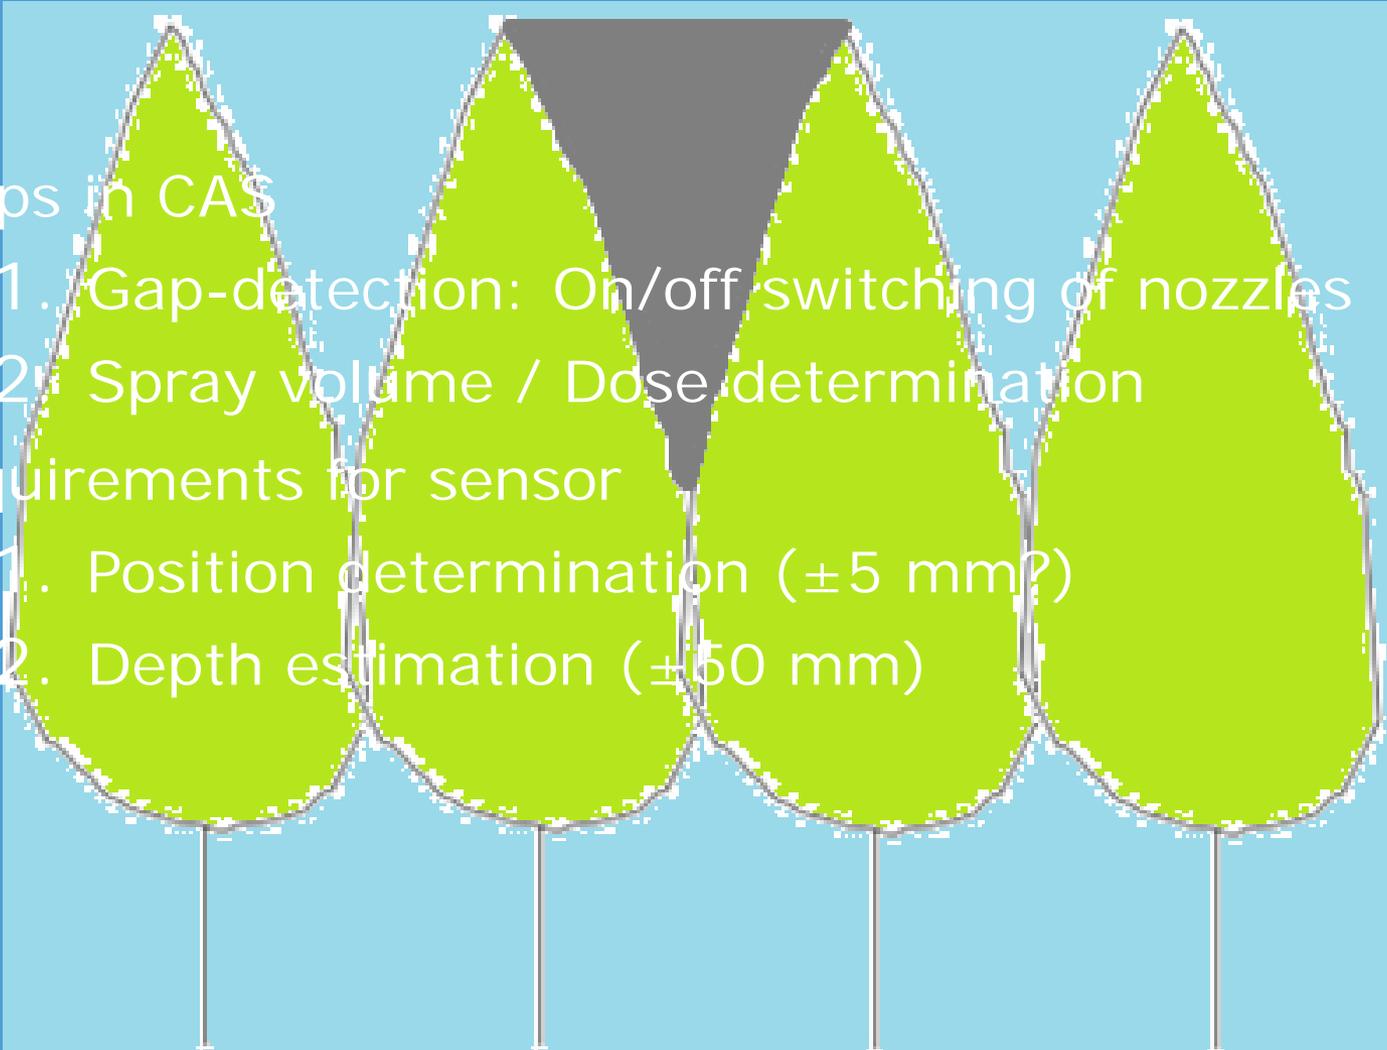

# Crop Adapted Spraying – desired situation

- Steps in CAS

1. Gap-detection: On/off switching of nozzles
2. Spray volume / Dose determination

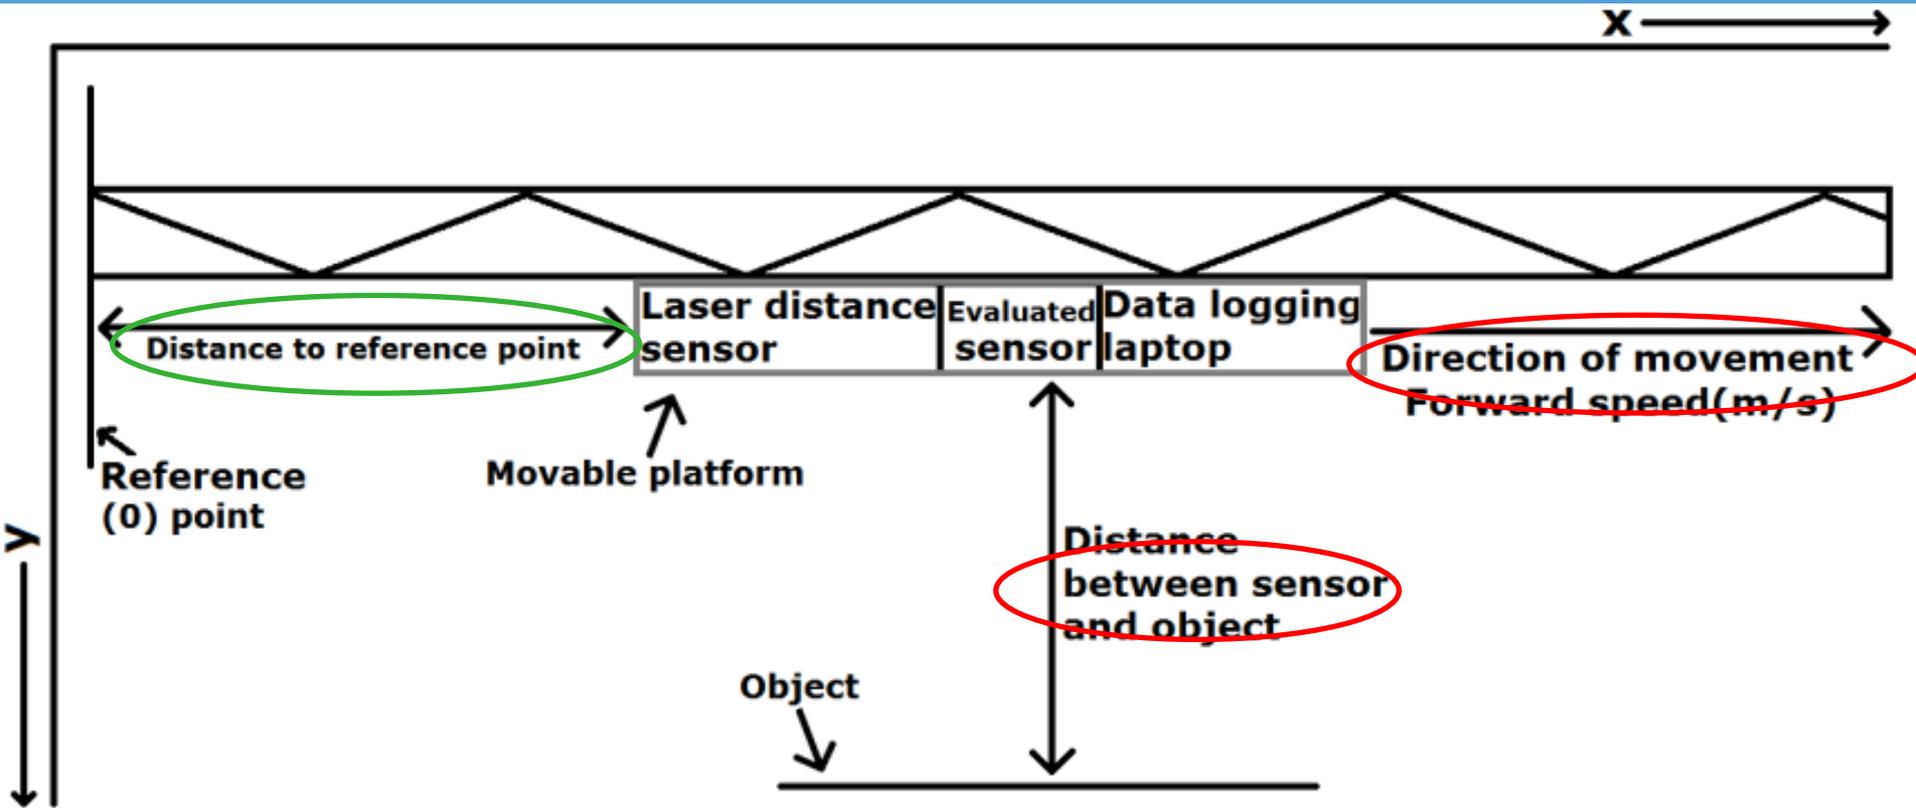

- Requirements for sensor

1. Position determination ( $\pm 5$  mm?)
2. Depth estimation ( $\pm 50$  mm)

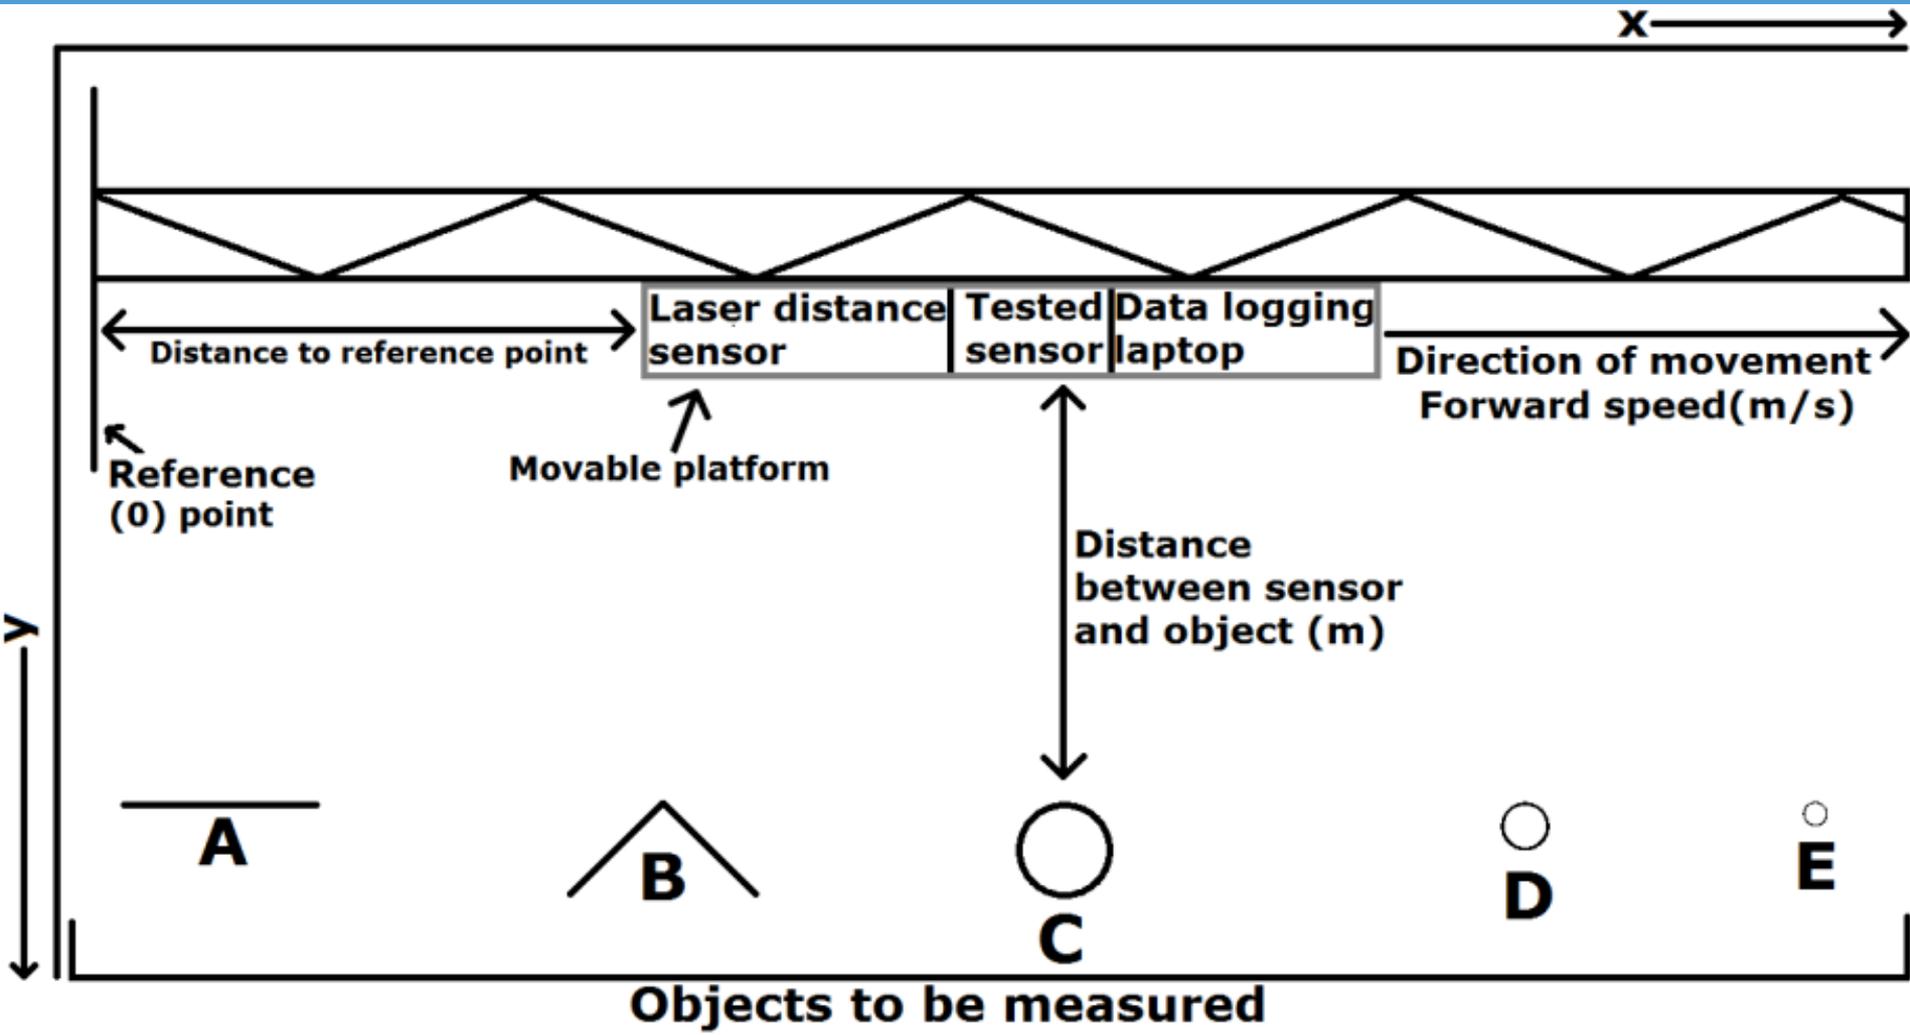

# Testbench sensors - calibration

## 1. Position determination ( $\pm 5$ millimetres)

## 2. Depth estimation ( $\pm 50$ millimetres)

# Testbench sensors - evaluation

# Ultrasonic Laser scanner

# WeedIt Kinect

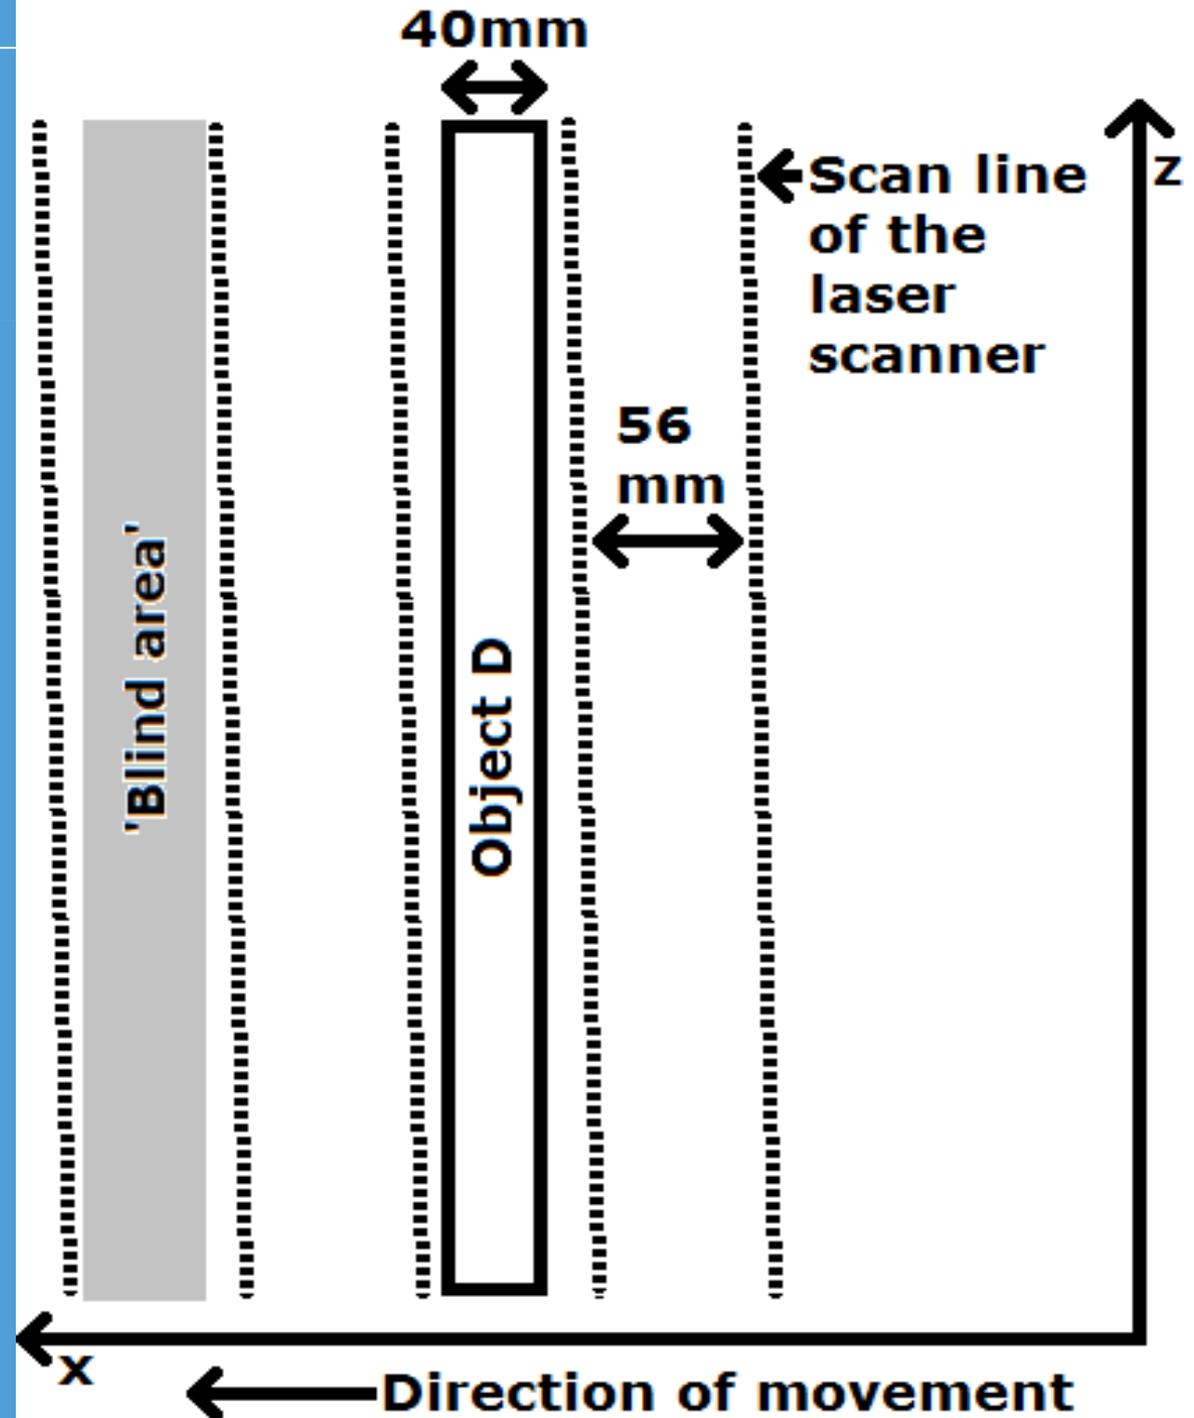

<b>Position determination (mm)</b>	$\pm 246$	$\pm 13.5$	$\pm 16$	$\pm 35.6$
<b>Depth estimation (mm)</b>	$\pm 36$	$\pm 25$		$\pm 8$

- Maximum forward speed for detecting object E, with a diameter of 16 millimetres, at least 9 out of 10 times when objects are placed at 750mm*

<b>Ultrasonic</b>	<b>Laser scanner</b>	<b>WeedIt</b>	<b>Kinect</b>
<b>0.1m/s</b>	<b>0.1m/s</b>	<b>1m/s</b>	<b>2m/s</b>

# Laser scanner

- Rotating; not looking at one side while looking at the other side;
- Needs time to transfer data after one rotation;
- Not looking at all to crop

---

# Disease & pest control →

support of crop health

---

- Detect crop vitality with sensors
  - Detect plant stress in an early stage
  - Increase plant natural resistance
  - Support the plant against diseases and pests
- 
- Development of Canopy Density & Health Sensor
  - Apply agrochemicals only on the areas where they are needed

# What to apply?

- Adaptation of spray volume to canopy structure
- Adaptation of dose to control pest & disease
- From kg/ha to kg/LWA product, is this the solution to all problems? Or just a first step in the direction of canopy adapted dose expression?
- Essential is: What is needed on what position in the tree to do the job!

# The challenge

- How to come from  $\text{ng}/\text{cm}^2$  product being effective to  $\mu\text{l}/\text{cm}^2$  spray volume to be applied and deposit on the target.

Especially when in-tree deposition differs per spray technique and sprayer and nozzle settings.

Thank you for  
your attention!
